

NGS and Genomes assemblies

Bioinformatics teachings

<http://bioinfomed.fr> - Olivier Croce (croce@unice.fr)

Data release

GenBank size

(GenBank.txt/gbrel.txt)

— (in blue) : history of bacterial genomes sequencing

Data release

- Submission of the sequence on public databases
- Not always => publication

3 main public databases:

- EMBL-EBI - ENA (European Nucleotide Archive)
<http://www.ebi.ac.uk/embl/>
- GenBank (USA) – NCBI
<http://www.ncbi.nlm.nih.gov/Genbank/>
- DDBJ (DNA DataBank of Japon) – CIB
<http://www.ddbj.nig.ac.jp/>

They are associated (International Nucleotide Sequence Database Collaboration) and exchange the same data which is periodically duplicated together

Contain:

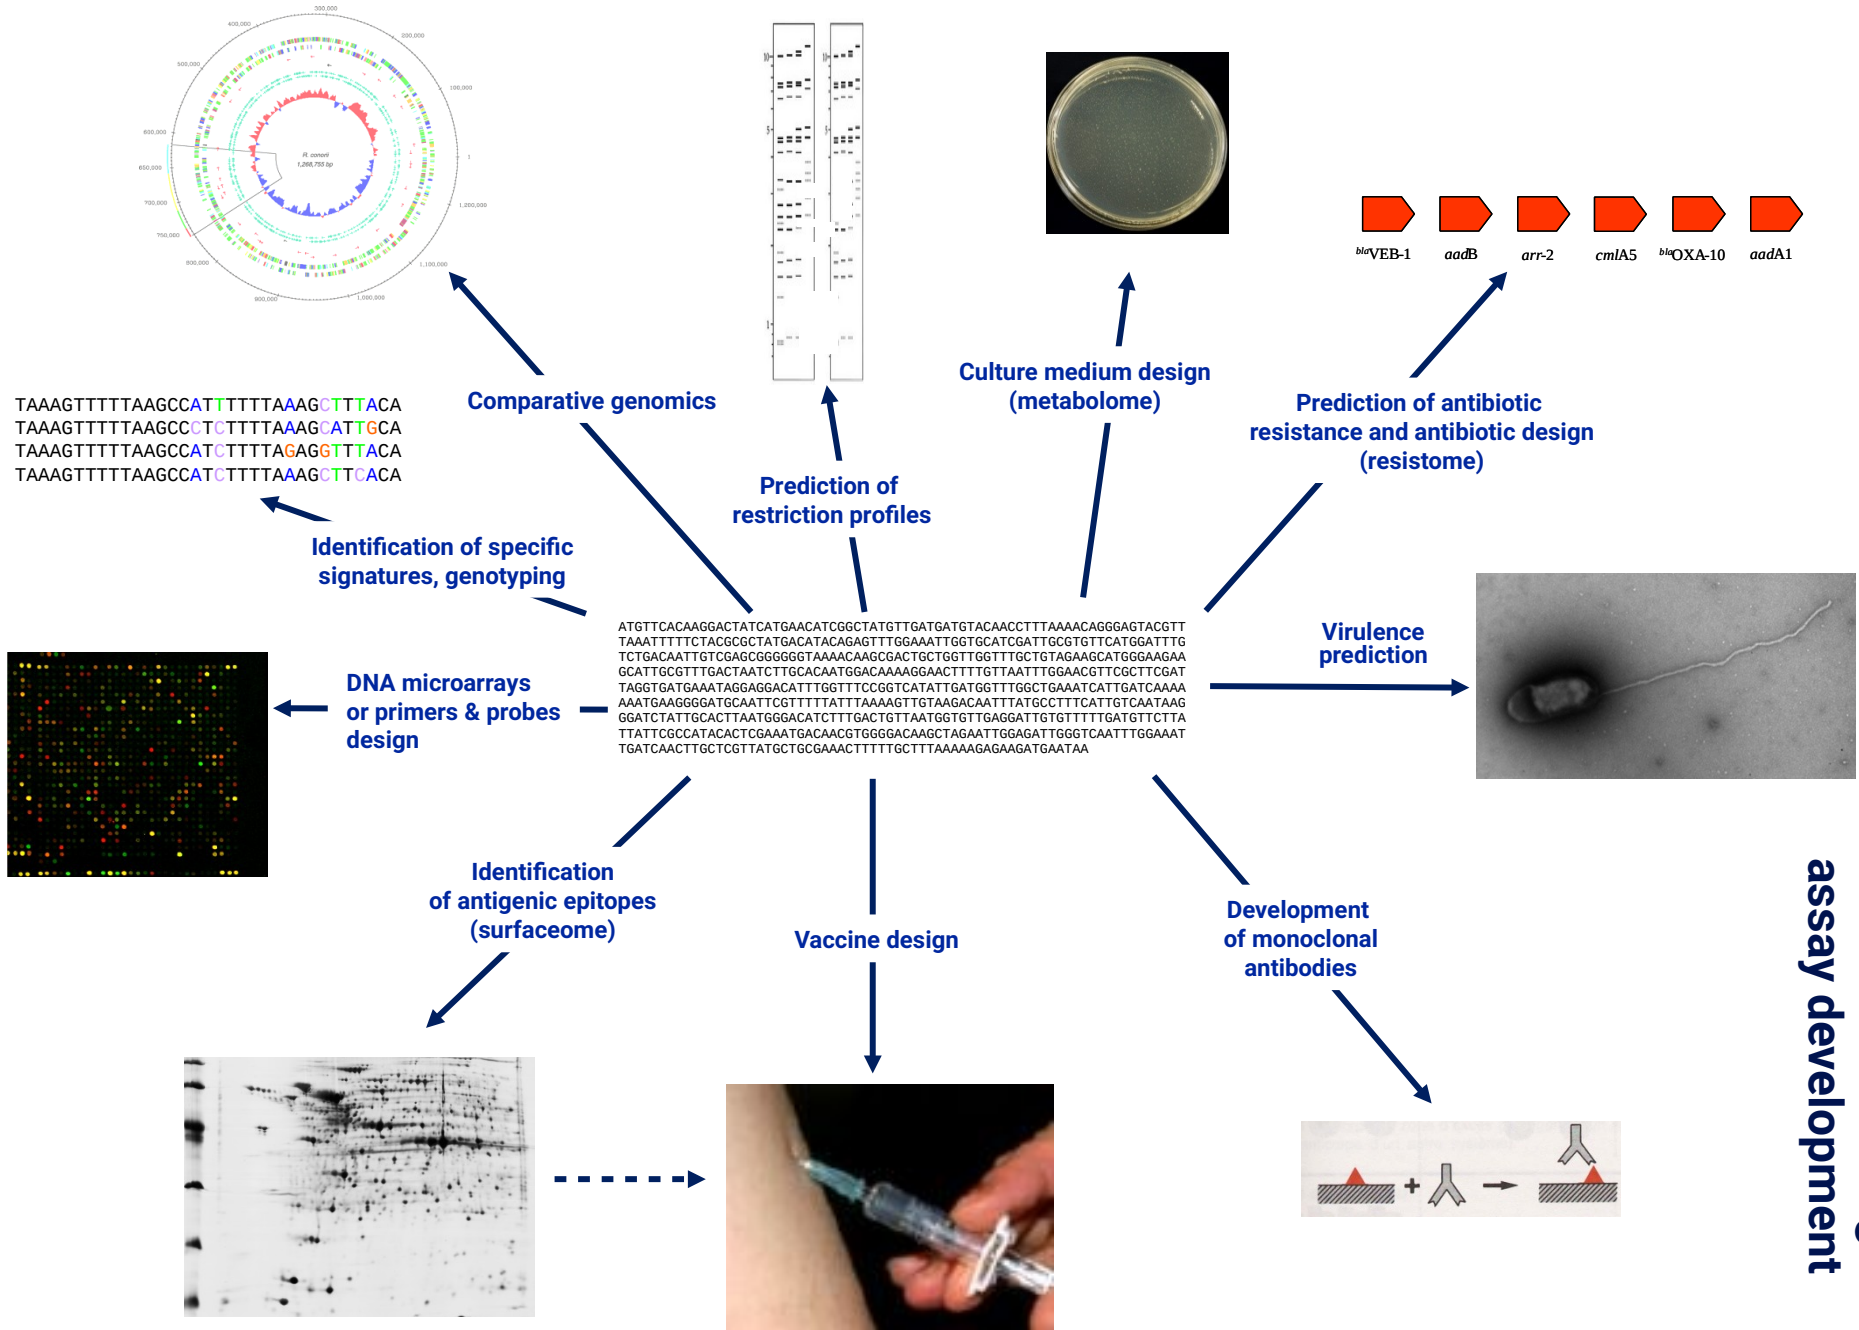

- Sequences of DNA or RNA from various sequencers technologies and from many labs
 - * Some genome fragments : one or more genes, intergenic sequences, parts of a genome
 - * Completed genomes
 - * mRNA, tRNA, rRNA (ie. 16s)
- Annotations

Aims

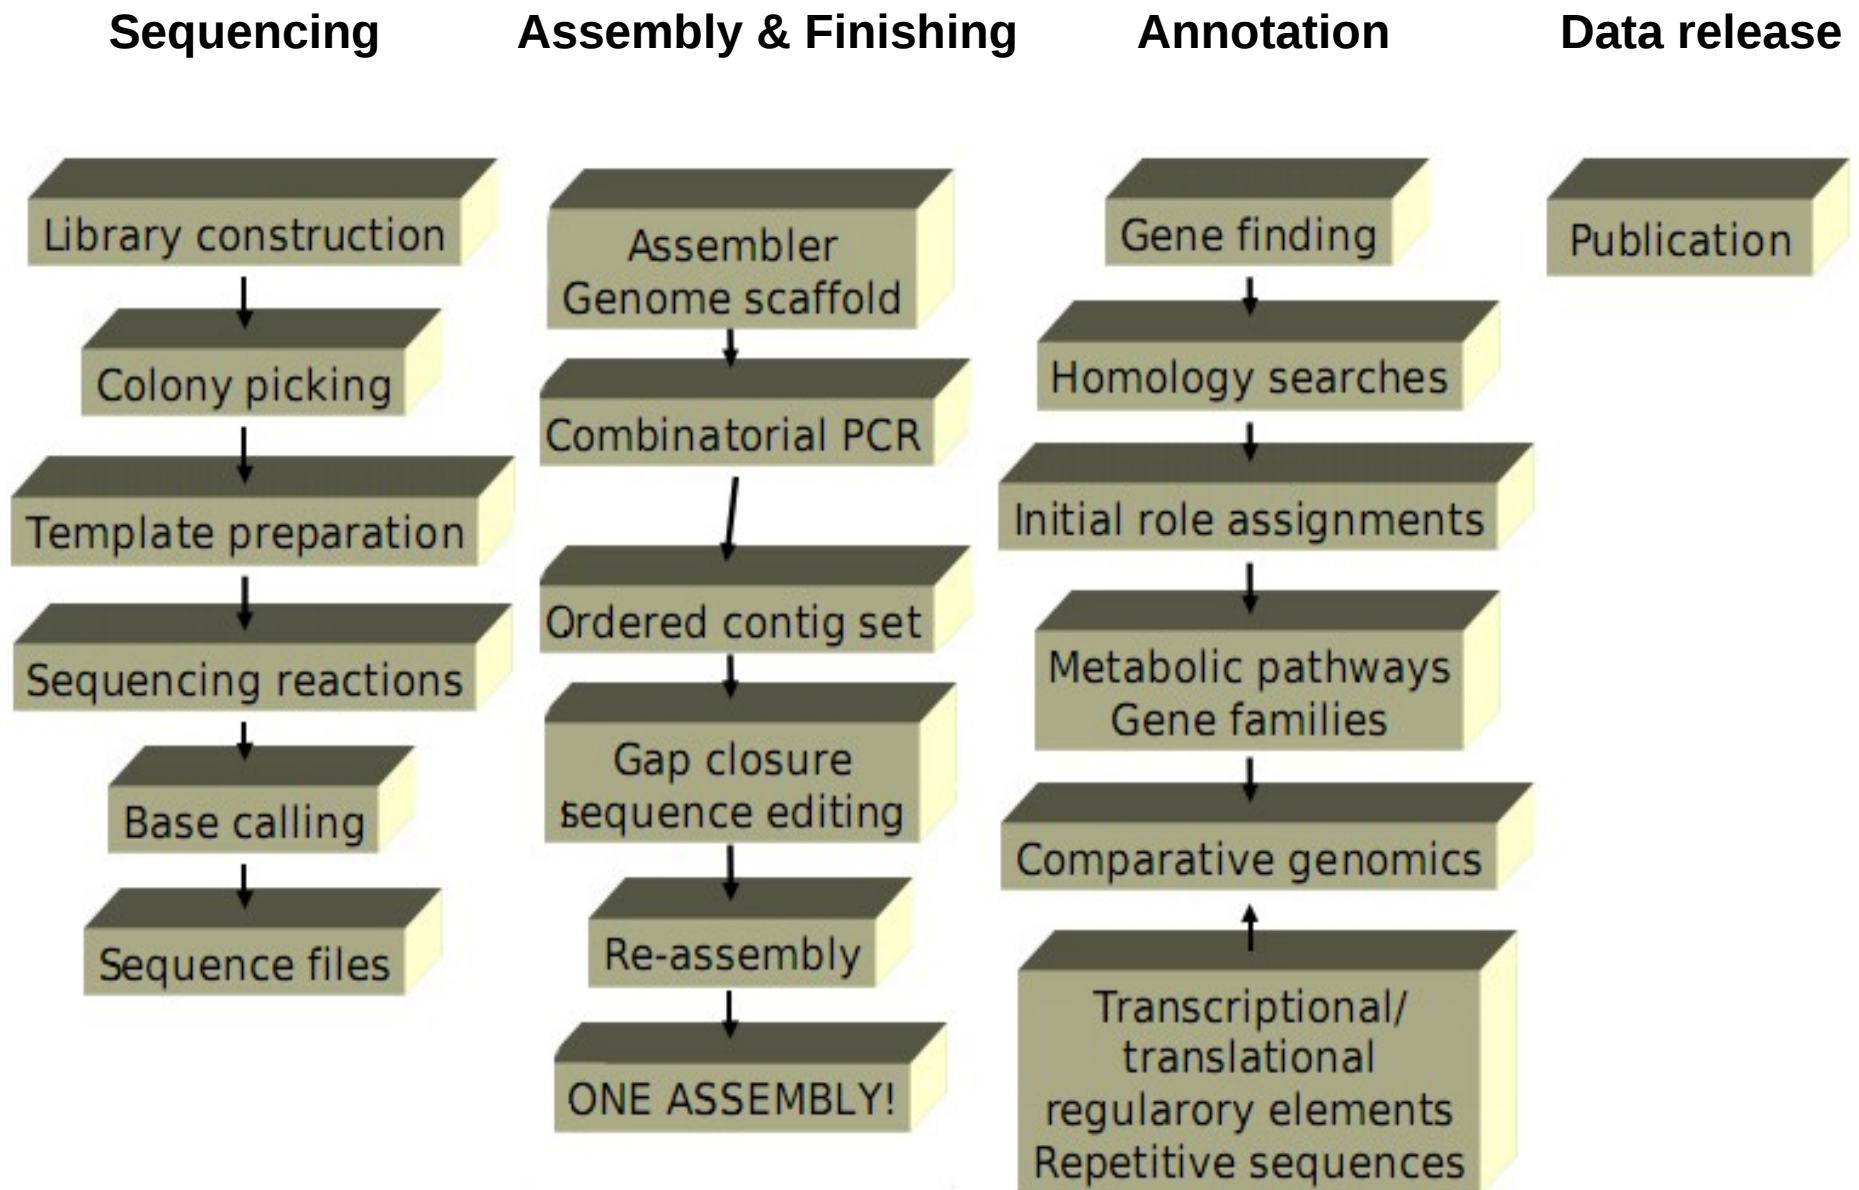

Molecular detection and identification

Phenotype prediction

Vaccine & serological assay development

From the bench to the publication

Quality level of genomes

- **The genome sequence must be completed with a high quality and annotated before the release**

Of course the best, but very time consuming.
Actually, 90-95 % of a microorganism genome could be easily covered without finishing, but the 5-10 % remained can take many weeks or months to be ended
=> now easier using long reads sequencing

- **The sequence should be uncompleted with a draft quality, whether we suppose most of the genes are sequenced (and identified)**

Many eukaryote genomes are only draft genomes, because of the complexity of finishing

=> In general, fundamental research usually performs high quality genomes and applicative research (industry, part of clinical) usually performs draft genomes

=> depending of the project : time and experience (bioinformatician), money (coverage of NGS), organisms, the question to answer

Sequencing technologies

Lex Nederbragt (2012-2016)
<http://dx.doi.org/10.6084/m9.figshare.100940>

Principle of sequencing and assembly

Sequencing step: reads have heterogeneous distribution

Assembly and finishing step

Principle of sequencing and assembly

ATCGATGCGTAGCAGACTACCGTTACGATGCCTT...
TAGCTACGCATCGTCTGATGGCAATGCTACGGAA...

Fragmentation + sequencing
=> sets of reads

TAGCTACGCATCGT
ATCGATGCGTAGC
TAGCAGACTACCGTT
GTTACGATGCCTT

ATCGATGCGTAGC
TAGCAGACTACCGTT
GTTACGATGCCTT
TGCTACGCATCG

→ CGATGCGTAGCA
(sequence inv-compl)

CGATGCGTAGCA
ATCGATGCGTAGC
TAGCAGACTACCGTT
GTTACGATGCCTT

Build of contigs with overlapping regions

Assembly :
=> alignements of reads + consensus

.....ATCGATGCGTAGCAGACTACCGTTACGATGCCTT.....

Principle of sequencing and assembly

Search for best pairings by comparing each sequence (and its reverse complement) against every others sequences to find the best overlapping

=> list of best candidates with similarities criteria

Best candidate is a compromise between :

- maximum overlap length - region of similarity between regions
- minimum overhang length - unaligned ends of the sequences
- maximum % identity in overlap region
- minimum repeat length

=> Many **assemblers** tools existed (depending of sequencings technologies, libraries, genomes size, etc..)

Constructions of library from genomes fragments

* **single - end (= shotgun)** : reads sequenced independently

* **paired-end** (similar to **mate-pair**) : reads are sequenced by pairs

- The distance between the reads is known (length of the insert), with some experimental uncertainty

- Distance of insert depends of technology (ie. Illumina ~150 nt for paired-end, ~1-5 kb mate-paired)

Why using PE/MP ? length of reads is limited => assemble repetitive regions by using reads as “anchors”

Contigs : group of overlapping reads, without gap

Scaffold : group of contigs order and in the same sens. Gap ("NNN") could existed and their length are known. Scaffolds exists only if a paired-ends (or mate pairs) sequencing was performed !

Mapped scaffolds : scaffolds mapped along a reference. Order, orientation and length of gaps are estimated, but not sure !

Main remaining problems

- Bad assembly of reads
- Low coverage of reads
- Bad insert size estimation
- Different orientation of contigs
- Error of sequencing
- Repeat sequence ambiguities

Re-Mapping, to see coverage, SNP and potential errors

Finishing

- (re)Mapping of reads along the assembled genome (or/and a reference)
- help to correct the low quality/coverage areas
- Check the order of contigs
- Check the redundancy of contigs (false contigs or true repeat contigs like rRNA operons)
- Compare synteny between multiple assemblers (global alignment)
- Fill the gaps by extending the boundaries of each gap using ends of mapping reads (or use PCR)
- Order (or reorder) contigs
- Desassemble some areas if they seem to be false

Bacillus cereus assemblies using 3 assemblers tools. 2 first genomes are very similar, the third show many differences

=> High improvement with new long-reads technology (Minlon Nanopore, PacBio)
